

CHEMICAL BONDS

IONIC, COVALENT, & METALLIC

FORMS OF CHEMICAL BONDS
Bonding: ionic, covalent, metallic

1. Ionic bonding: transfer of electrons between atoms, forming ions that are held together by electrostatic forces.

2. Covalent bonding: sharing of electron pairs between atoms.

3. Metallic bonding: delocalized electrons in a lattice of positive ions.

CHEMICAL BONDS AND QUANTUM MECHANICS

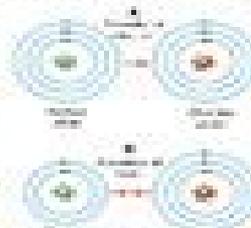

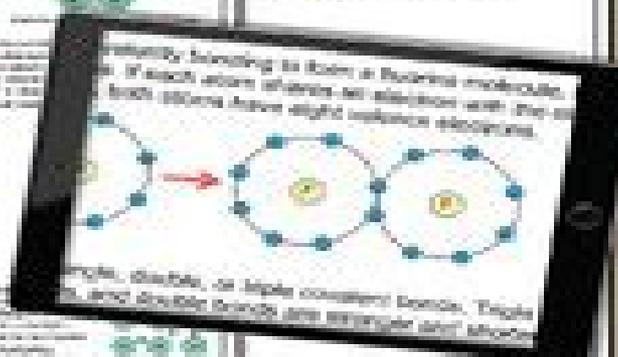

Quantum mechanics explains the behavior of electrons in atoms and molecules. It shows that electrons do not orbit the nucleus in simple paths, but exist in probability clouds called orbitals. The energy levels of these orbitals determine the types of chemical bonds that can form.

Diagram illustrating the formation of an ionic bond between a sodium atom (Na) and a chlorine atom (Cl). The sodium atom has one valence electron, and the chlorine atom has seven valence electrons. The sodium atom loses its valence electron to the chlorine atom, forming a sodium cation (Na⁺) and a chloride anion (Cl⁻). The resulting ionic bond is shown as a pair of oppositely charged ions held together by electrostatic attraction.

Diagram illustrating the formation of a covalent bond between two carbon atoms (C). Each carbon atom has four valence electrons. The two carbon atoms share their valence electrons to form a covalent bond, resulting in a carbon-carbon molecule (C₂).

Diagram illustrating the formation of a metallic bond in a metal lattice. The metal atoms are shown as a lattice of positive ions, and the valence electrons are delocalized, forming a "sea of electrons" that holds the lattice together.
