Gene Mutations and Traits

Genes are instructions found on chromosomes made up of DNA. These instructions tell cells how to make proteins. Proteins are important molecules that help determine an organism's traits, such as hair color, height, or the ability to digest certain foods. Each gene codes for a specific protein, and the sequence of DNA in a gene decides how that protein is made.

Sometimes, changes can happen in the DNA sequence of a gene. These changes are called mutations. Mutations can alter the protein that the gene codes for. Some mutations may cause the protein to work differently, or not work at all. This change in the protein can affect the traits of the organism, sometimes causing harmful effects, sometimes beneficial effects, or sometimes no noticeable effect at all.

For example, a mutation in a gene that controls pigment production in flowers might change the color of the petals. If the protein changes so that it produces a different pigment, the flower's color changes. This is a visible trait change caused by a mutation. Scientists use models to help understand how changes in genes lead to changes in proteins and traits. These models can show how a mutation in DNA leads to a different protein and then to a change in a trait that can be observed.
