1. Match each of the following changes in DNA sequence structure to its definition:

A. Deletion

B. Duplication

C. Inversion

D. Translocation

a. a section of a chromosome is inserted

b. a piece of a chromosome is deleted

c. a segment of one chromosome has moved (inverted) to a different, non-homologous chromosome

d. a section of a chromosome appears to be on one chromosome but is not

2. How many genetically different gametes can be produced from a diploid cell with four chromosomes pairs? Describe your answer.

Match the number of genetically different gametes that can be produced to each of 2ⁿ where n is total number chromosomes pairs, a diploid cell with four chromosomes pairs can produce gametes of 16 or 32 genetically different gametes

3. Although your offspring is a combination of both of your genes, you recognize that some traits come from one independent chromosome. For example, both of your eyes are blue. Why may some traits be inherited together?

They have been linked together and travel on the same chromosome. Traits that are independent assortment are not, and a heterozygous-diploid only makes only one heterozygous chromosome. Some traits will be inherited together and some will be inherited separately. Mendel's theory will be inherited together.

4. Describe the alignment of chromosomes during prophase I, write the equations:

Homologous chromosomes I chromosomes crossing and homologous chromosomes align together, called synapsis. This is a synapsis because it shows the crossing over of chromosomes and results in two double chromosomes.

5. How does recombination lead to chromosomes with recombinant genes? Describe how types of genetic variation that can result from recombination.
